

# Estimating bayesian mutliple graphical models with EM

Luca Bracone

December 8, 2022

# Undirected bayesian graph

There is an edge  $(i, j)$  if and only if  $y_i \not\perp y_j | y_{-i-j}$

# Setting and assumptions

We observe  $p$  parameters across  $n$  samples. That is we have  $n$  observations  $y^1, \dots, y^n \in \mathbb{R}^p$  of a  $p$  dimensional vector. We assume that  $y^1, \dots, y^n \stackrel{i.i.d.}{\sim} \mathcal{N}_p(0, \Sigma)$  have a multivariate normal distribution.

- ▶ To estimate the graph we would like to know whether  $y_i \perp\!\!\!\perp y_j \mid y_{-i,-j}$ .
- ▶ Idea: We know that in the *precision matrix*,  $\Omega = \Sigma^{-1}$  the  $(i, j)$ -th entry is zero only if  $y_i \perp\!\!\!\perp y_j \mid y_{-i,-j}$
- ▶ How do we find the zero entries of  $\Omega$  ?

# Why should we use the Bayesian method ?

- ▶ Flexible hierarchical modeling
- ▶ Ease of interpretation of results
- ▶ Use prior knowledge

If we consider  $\Omega$  as being drawn from a prior distribution  $p(\Omega)$  we can obtain a *posterior distribution*  $p(\Omega|X)$  of which the maximum is the *maximum à-posteriori* estimate  $\Omega$ .

# Spike and slab prior

The spike and slab prior for  $\Omega$  helps us differentiate between zero and non-zero entries of  $\Omega$

$$\begin{aligned}y|\Omega &\sim N_p(0, \Omega^{-1}), \\ \omega_{ij}|\delta_{ij} &\sim \delta_{ij}N(0, v_1^2) + (1 - \delta_{ij})N(0, v_0^2), i \neq j, \\ \omega_{ii} &\sim \text{Exp}(\lambda/2), \\ \delta_{ij}|\pi &\sim \text{Bern}(\pi), \\ \pi &\sim \text{Beta}(a, b).\end{aligned}$$

# Posterior joint distribution

After a few manipulations we find that

$$p(\Omega, \delta, \pi | y) \propto p(y | \Omega) p(\Omega | \delta) p(\delta | \pi) p(\pi)$$

$$\log(p(\Omega, \delta, \pi | Y)) =$$

$$\begin{aligned} & \sum_{j < k} -\log(v_0^2(1 - \delta_{jk}) + v_1^2\delta_{jk}) - \frac{\omega_{jk}^2}{2} \frac{1}{v_0^2(1 - \delta_{jk}) + v_1^2\delta_{jk}} - \sum_j \frac{\lambda}{2} \omega_{jj} \\ & + \sum_{j < k} \delta_{jk} \log\left(\frac{\pi}{1 - \pi}\right) + \log(1 - \pi) \\ & + (a - 1) \log(\pi) + (b - 1) \log(1 - \pi) \\ & + \frac{n}{2} \log \det(\Omega) - \frac{1}{2} \text{tr}(Y^t Y \Omega) + \text{constants.} \end{aligned}$$

## Taking expectations

$$\begin{aligned} Q(\Omega, \pi | \Omega^{(l)}, \pi^{(l)}) &= E_{\delta | Y, \Omega^{(l)}, \pi^{(l)}} (\log(p(\Omega, \delta, \pi | Y) | Y, \Omega^{(l)}, \pi^{(l)})) = \\ &= - \sum_{j < k} \frac{\omega_{jk}^2}{2} E_{\delta_{jk} | \cdot} \left( \frac{1}{v_0^2(1 - \delta_{jk}) + v_1^2 \delta_{jk}} \right) - \sum_j \frac{\lambda}{2} \omega_{jj} \\ &+ \sum_{j < k} E_{\delta_{jk} | \cdot} (\delta_{jk}) \log \left( \frac{\pi}{1 - \pi} \right) + \log(1 - \pi) \\ &+ (a - 1) \log(\pi) + (b - 1) \log(1 - \pi) \\ &+ \frac{n}{2} \log \det(\Omega) - \frac{1}{2} \text{tr}(Y^t Y \Omega) + \text{constants}. \end{aligned}$$

## Computing expectation terms

$$q_{jk} := E_{\delta_{jk}|\cdot}(\delta_{jk}) = \frac{\pi p(\omega_{jk}|\delta = 1)}{\pi p(\omega_{jk}|\delta = 1) + (1 - \pi)p(\omega_{jk}|\delta = 0)}.$$

And

$$d_{jk} := E_{\delta_{jk}|\cdot} \left( \frac{1}{v_0^2(1 - \delta_{jk}) + v_1^2\delta_{jk}} \right) = \frac{1 - q_{jk}}{v_0^2} + \frac{q_{jk}}{v_1^2}$$

# Maximising $\pi$

Taking the derivative and setting to zero we find that

$$\pi^{(l+1)} = \frac{a - 1 + \sum_{j < k} q_{jk}}{a + b - 2 + \frac{p(p-1)}{2}}$$

## Maximising $\Omega$

If we partition

$$\Omega = \begin{pmatrix} \Omega_{11} & \omega_{12} \\ \omega_{12}^t & \omega_{22} \end{pmatrix} \quad X^t X = \begin{pmatrix} S_{11} & s_{12} \\ s_{12}^t & s_{22} \end{pmatrix}$$

we find that

$$\omega_{12} \sim N(-C^{-1}s_{12}, C) \quad C = (s_{22} + \lambda)\Omega_{11}^{-1} + \text{diag}(v_{12}^{-1})$$

and that

$$\omega_{22} \sim \text{Gamma}\left(\frac{n}{2} + 1, \frac{s_{22} + \lambda}{2}\right) + \omega_{12}^t \Omega_{11}^{-1} \omega_{12}.$$

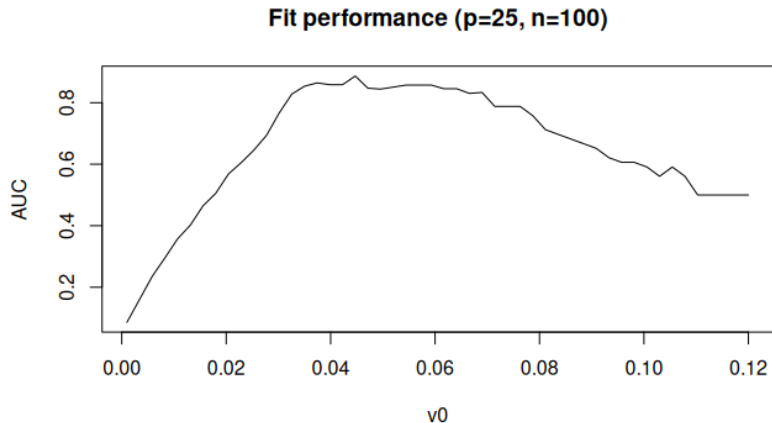

Taking the modes we find the update steps

$$\omega_{12}^{(l+1)} = -((s_{22} + \lambda)\Omega_{11}^{-1} + \text{diag}(d_{12}))^{-1}s_{12}$$

$$\omega_{22}^{(l+1)} = \frac{n}{s_{22} + \lambda} + (\omega_{12}^{(l+1)})^t \Omega_{11}^{-1} \omega_{12}^{(l+1)}$$

# Choosing hyperparameters

Big influence on performance

## Try: fixing sparsity

Say I know I want about  $s = 10\%$  sparsity.

- ▶ Then fix  $a, b$  so that  $a/(a + b) = s$
- ▶ Try many  $v_0$ , pick fit with closest sparsity.

# Effect on performance

Method	EMGS	MB
$p=25$	0.86	0.45
$p=35$	0.78	0.54
$p=50$	0.72	0.52

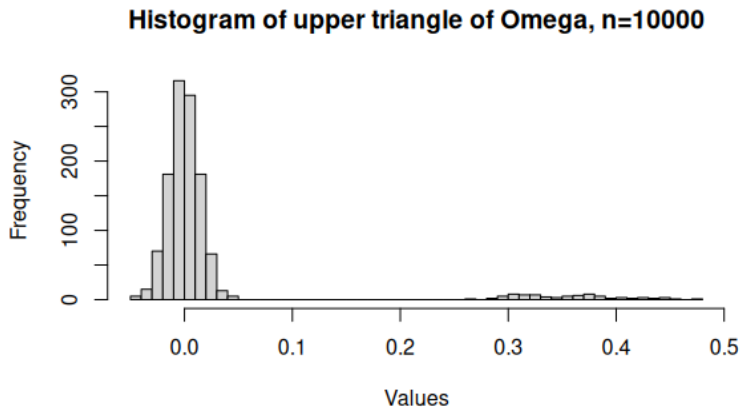

Table: AUC values for  $n = 100$ ,  
 $p=25, 35, 50$

# How to choose sparsity?

Fitting gaussian mixture model, not very convincing.

It will depend on generation method

## Future work

The original aim of the project: multiple graphs. We now have a hierarchical model

$$\begin{aligned}y|\Omega_k &\sim N_p(0, \Omega_k^{-1}), \\ \omega_{ijk}|\delta_{ijk} &\sim \delta_{ijk}N(0, v_1^2) + (1 - \delta_{ijk})N(0, v_0^2) \text{ for } i \neq j, \\ \omega_{iik} &\sim \text{Exp}(\lambda_k/2), \\ \delta_{ijk}|\theta_{ijk} &\sim \text{Bern}(\Phi(\theta_{ijk})), \\ \theta_{ij} &\sim N_K(0, \Sigma).\end{aligned}$$

The parameter  $\Sigma$  is a shared parameter across graphs.
